Abstract

The sonocatalytic degradation of organic dyes (C.I. 50040, C.I. Reactive Red 1, C.I. Acid Orange 7) catalysed by $Co/N/Er^{3+}$: Y₃Al₅O₁₂/TiO₂ films was studied. For the preparation of Co/N/Er³⁺: Y₃Al₅O₁₂/TiO₂ films, the sol-gel coating process was used. The phase composition, morphology, precursor at different temperatures and emitting light properties of the calcined powders were analysed by X-ray diffraction (XRD), absorption spectra and upconversion emission spectra. The X-ray diffraction of powder samples of Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ took on anatase mine peaks and upconversion luminous agent, respectively. Analysis of absorption spectra of amorphous $Co/N/Er^{3+}$: Y₂Al₅O₁₂/TiO₂ showed that doping N stretching vibration peak of water or hydroxyl adsorption, Co^{2+} ion had very strong absorption in 1.0–1.7 μ m wavelength range, the transition luminescence of Er³⁺ ions was just on Co²⁺ ions absorption band. The emission spectrum indicated that Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ could launch green 500–560 nm and red 650–700 nm, 525, 550 and 660 nm peaks corresponding to ${}^{2}H_{11/2}$, ${}^{4}S_{3/2} \rightarrow {}^{4}I_{15/2}$ and ${}^{4}H_{9/2} \rightarrow {}^{4}I_{15/2}$ transition of Er³⁺. Doping Co and N enhanced the upconversion luminescence and absorption effect. Sonocatalytic degradation effect of organic dyes loading Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ was better when ultrasonic intensity was equal to 15 W cm⁻². The degradation ratios of aqueous solutions of these three kinds of organic dyes by ultrasonic irradiation were obviously lower than by ultrasonic irradiation together with $Co/N/Er^{3+}$: Y₃Al₅O₁₂/TiO₂ films in the same conditions. Degradation kinetics of organic dyes by ultrasonic irradiation and by ultrasonic irradiation cooperating with Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ films followed the first-order reaction.

Key words

Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂, upconversion emission spectra, sonocatalytic, dye degradation

Introduction

Recently, photocatalytic degradation of organic pollutants assisted by TiO₂ has been extensively investigated because of its strong oxidation ability, low energy consumption, and simple operation.^{1,2} The discharge from the textile industries contains a lot of inorganic salts and surface-active agents. Inorganic salts and surfactants have complicated influence on the photocatalytic treatment processes of dye effluents.³ The research of E. Y. Bae et al.^{4,5} manifested that the ultrasonic mineralization aided efficiently in opaque or low transparent degradation of dye effluents. K. Okitsu et al.^{6,7} reported ultrasonic and solar photocatalytic decomposition of organic dye in aqueous solution. Owing to broadband gap of TiO₂, only a small fraction (ultraviolet light) of sonoluminescence could be taken advantage of in sonocatalytic degradation. According to J. Wang et al.^{8,9,10} the upconversion luminescence agent could transform visible light into ultraviolet light, which might activate the TiO₂ efficiently. Moreover, some semiconductor materials uniting some upconversion luminescence agent may improve the catalytic degradation efficiency for further expanding the spectral response range of ultrasound catalysis.

The preparation of Co/N/Er³⁺ : $Y_3AI_5O_{12}$ /TiO₂ and the characterization of XRD are presented. This study details the ef-

fects on crystal structure, spectra, degradation efficiency of organic dye in sonocatalytics of Co/N/Er³⁺ : $Y_3Al_5O_{12}/TiO_2$.

Experimental

Materials

 Y_2O_3 (purity 99 %), Er_2O_3 (purity 99 %), CoO (purity of 99 %), HNO₃ (analytically pure) (Veking Company, China) and Al(NO₃)₃ · 9H₂O were used to prepare Co/N/Er³⁺ : Y₃Al₅O₁₂. Diethanolamine (C₄H₁₁NO₂), tetrabutyl titanate (Ti(OC₄H₉)₄), ethanol (C₂H₆O), H₂O, acetic acid (CH₃COOH), and polyethylene glycol 3000 (HO(CH₂CH₂O)nH) were used to synthesize TiO₂ gel.

C.I. 50040 ($C_{15}H_{17}CIN_4$), C.I. Reactive Red 1 ($C_{19}H_{10}$ - $CI_2N_6O_7S_2Na_2$) and C.I. Acid Orange 7 ($C_{16}H_{11}N_2NaO_4S$) (99.99 % purity) were obtained from Tianjin Kaiyuan Reagent Corporation (China). Their characteristics are listed in Table 1.

Synthesis of Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂

 Y_2O_3 , Er_2O_3 and CoO (the molar ratio of Er^{3+} : Co^{2+} : Y^{3+} equal to 1 : 9 : 90) were dissolved in HNO₃, and excess HNO₃ was evaporated to obtain the lanthanide nitrates. Second, $Al(NO_3)_3$ (moles ratio of $[Y(NO_3)_3 + Er(NO_3)_3]$ and $Al(NO_3)_3 = 3 : 5$) was added to the lanthanide nitrates, which were then *N*,*N*-dimethylformamide to produce Co/N/Er³⁺ : Y₃Al₅O₁₂ solution.

Table 1– Characteristics of organic dyesTablica 1– Karakteristike organskih bojila

In the preparation of composite TiO₂ gel, the molar ratio of diethanolamine : tetrabutyl titanate : ethanol : H₂O : acetic acid : polyethylene glycol 3000 was equal to 2 : I : 20 : 2 : 0.3 : 0.002. First, tetrabutyl titanate and diethanolamine were added into ethanol and agitated for 1 hour with magnetic stirrer against white flocculent precipitation. Deionized water and acetic acid were then dripped in slowly and at the same time agitated for 10 minutes. Next, the above Co/N/Er³⁺ : Y₃Al₅O₁₂ solution was dripped in and stirred at the same time, after which polyethylene glycol 3000 was added, and stirred for another 3 hours. Finally, Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ gel was prepared.

The glass slides were cleaned and dried with deionized water and ultrasonic wave. $Co/N/Er^{3+}$: $Y_3Al_5O_{12}/TiO_2$ gels were sprayed on glass slides by ultrasonic spraying equipment (Beijing Dongfang Jinrong ultrasonic electric Co. Ltd.). Spraying width was 20 mm, the flow rate was 10 ml min⁻¹. After the wet films had dried, they were put into the heating furnace for heat treatment, with 2 °C min⁻¹ up to 120 °C, with 120 min insulation, in order to strengthen the porous thin films of Co/N/Er³⁺ : Y_3Al_5O_{12}/TiO_2.

Sonocatalytic degradation of the organic dye

The experimental apparatus is shown in Fig. 1. The reactor with a built-in trough was placed on a magnetic stirrer. The glass slides with Co/N/Er³⁺ : $Y_3AI_5O_{12}$ /TiO₂ thin films were inserted into the trough. The glass slides had tiny holes so that dye solutions could pass through them to distribute homogeneously in the degradation process. The ultrasonic probe (model of ultrasonic generator: 88-1, frequency: 22 kHz) was put into the reactor. The samples of three kinds of dye solutions (C.I. 50040, C.I. Reactive Red 1, C.I. Acid Orange 7) in the reactor were dispersed under ultrasonic irradiation for 120 minutes, while sampled once every 20 minutes, which immediately dispersed by centri-

fuging 15 minutes at 6000 r min⁻¹. Each test was repeated three times, and the averages of tests were taken.

The concentrations of the samples were measured by an Aquamate[™] Plus UV-vis spectrophotometer (Thermo Scientific Company). The concentrations of C.I. 50040, C.I. Reactive Red 1, and C.I. Acid Orange 7 were determined at their respective maximum absorbance.

Analytical method

The X-ray diffractometer (Model: D8 Advance) was used to characterize the samples of $Co/N/Er^{3+}$: $Y_3AI_5O_{12}/TiO_2$ nanoparticles. The upconversion emission spectra of the samples were tested by Hitachi F-4500 fluorescence spectrometer. The UV/VIS/NIR spectrometer (Model: V-570JASCO) was used to analyse the absorption spectrum at ambient temperature. The absorbance of dye solution was determined by Shimadzu 2450 UV-vis spectrophotometer.

Results and discussion

Characterization

Firstly, Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ gels were heated to 90 °C for 1 hour, and then milled into fine powders. Second, they were put into the muffle furnace (Model: DC-B8/12) to calcine at 1160 °C for 2 hours, and then cooled to ambient temperature. Fig. 2 illustrates their X-ray diffraction pattern. The main characteristic diffraction peaks appeared at $2\theta = 18.2^{\circ}$, 25.6°, 27.4°, 29.8°, 33.6°, 41.1°, 46.6°, and 55.1°. Compared JCPDS card, they were the characteristic diffraction peaks of the anatase and the upconversion luminous agent, respectively. The characteristic diffraction peaks broadened owing to doping Co and N in Fig. 2.

Spectral characteristics

The absorption spectra of crystalline $Co/N/Er^{3+}$: Y₃Al₅O₁₂/ TiO₂ is illustrated in Fig. 3. Doping N could broaden vibration peak of the adsorption of water or hydroxyl and Ti–O vibration peak that had been stretched and shifted to lower wavenumbers. Co2+ ions had strong absorption band at 1.0 – 1.7 μm wavelength range, the transition luminescence of Er^{3+} ions was just in Co^{2+} ions absorption band. The absorption peak at 1.55 µm was just corresponding to ${}^{4}A_{2} \rightarrow {}^{4}T_{1}$ (⁴F) energy level transition of Co²⁺. The absorption curve, near $1.47 \sim 1.55 \,\mu\text{m}$ was not gentle mainly because of the absorption transition of Er^{3+} ions. In Fig. 4, the emission spectrum of the test show that: $Co/N/Er^{3+}$: Y₃A- I_5O_{12}/TiO_2 could emit green 500–560 nm and red 650–700 nm, with peaks in 525, 550 and 660 nm, corresponding to $^2H_{11/2},\ ^4S_{3/2}\rightarrow\ ^4I_{15/2}$ and $^4H_{9/2}\rightarrow\ ^4I_{15/2},$ energy level transition of Er³⁺. Doping Co and N could broaden the absorption peak and strengthen upconversion emission.^{11,12}

Effects of ultrasonic intensity on the degradation of dye

In three kinds of dye (C.I. 50040, C.I. Reactive Red 1, C.I. Acid Orange 7) degradation test, the mass concentrations of the dye solutions were all 50 mgl⁻¹ and the loading qual-

ities of Co/N/ Er^{3+} : Y₃Al₅O₁₂/TiO₂ films were all 2.0 g L⁻¹. Fig. 5 shows the degradation ratios of these three kinds of dye when ultrasonic intensities were 5, 10, 15, and 20 W cm⁻² respectively. At 120 minutes, the degradation ratios (γ_t/γ_0) of C.I. 50040 solution reached 22.14 %, 15.36 %, 5.89 %, and 4.97 %, those of C.I. Reactive Red 1 were 24.01 %, 17.48 %, 8.24 %, and 5.84 %, and those of C.I. Acid Orange 7 were 18.79 %, 13.22 %, 5.292 %, and 4.15 %, respectively, when ultrasonic intensities were 5, 10, 15, and 20 W cm⁻² respectively. Apparently, the degradation ratios $((\gamma_t/\gamma_0))$ of these three kinds of dye decreased with the increasing of ultrasonic irradiation time and ultrasonic intensity. The decrease in the value of (γ_t/γ_0) was more obvious when the ultrasonic intensity increased from 5 to 15 W cm⁻² than when the ultrasonic intensity increased from 15 to 20 W cm⁻². The reason might be that, when the ultrasonic intensity became largely excessive, the cavitation bubbles became too big in the negative phase of the sound wave to collapse sufficiently so that available ultrasonic energy decreased, thus forming a sound shield. Furthermore, when ultrasonic intensity was 20 W cm⁻², the ultrasonic generator could overheat and the ultrasonic probe surface could corrode significantly for cavitation. Therefore, the sound intensity, 15 W cm⁻², was suggested in the ultrasonic degradation experiments.

Figs. 6a, 6b, and 6c illustrate the degradation ratios of the aqueous solutions of C.I. 50040, C.I. Reactive Red 1, and C.I. Acid Orange 7 with the time, respectively. Firstly, it can be seen that, for these three kinds of dye solutions, the

C.I. Acid Orange 7	0.00369	0.99876	0.0316	0.99878	

degradation ratios all increased with the increase in time of ultrasonic irradiation. Secondly, it can be noted that the degradation ratios of C.I. 50040, C.I. Reactive Red 1, and C.I. Acid Orange 7 only under ultrasonic radiation were obviously lower than those under ultrasonic radiation and loading catalysts of Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ films. This might be because ultrasonic cavitation could have produced free radicals OH, which could have oxidized the dye molecules, but the dye molecular structure was too stable to be degraded easily only under ultrasonic radiation. Co/N/ Er^{3+} : Y₃Al₅O₁₂/TiO₂ films had very large specific surface and thus relatively more catalytic active points. These contributed to the change of the charged properties and space configuration of dye molecules adsorbed by catalyst surface, which could improve the adsorption efficiency of surface active points, that is, make the surface radicals (OH) oxidize the dye molecules easier. This corresponds to the bond (-N=N-) as the most active site for oxidative attack in dye molecule of C.I. 50040, C.I. Reactive Red 1, and C.I. Acid Orange 7.

Research on the sonocatalytic reaction kinetics was also conducted. The reaction rate constant and reaction order were determined by differential method.

The reaction rate equation was

$$v_t = -\frac{dc_t}{dt} = kc_t^n \tag{1}$$

where, v_t is the reaction rate at time t, c_t is the reaction concentration at time t, k is the reaction rate constant, and superscript n is the reaction order.

Taking logarithm on both sides of Eq. (1), we could obtain the following equation

$$\lg v_t = \lg k + n \lg c_t \tag{2}$$

According to Eq. (2), and using the reaction concentration and reaction rate measured in degradation tests, the reaction rate constant and reaction order were evaluated as shown in Table 2. The sonocatalytic degradation reactions all followed the first-order kinetics.

Conclusions

 $Co/N/Er^{3+}$: Y₃Al₅O₁₂/TiO₂ films were prepared by sol-gel coating process. They were characterized by XRD, presenting the characteristic diffraction peaks of the anatase and the upconversion luminous agent, respectively. From the absorption and emission spectra figures, doping Co and N contributed to the absorption and upconversion emission effect. In the degradation tests of C.I. 50040, C.I. Reactive Red 1, and C.I. Acid Orange 7, the ultrasonic intensity 15 W cm⁻² was recommended. The degradation ratios of aqueous solutions of these three kinds of organic dyes by ultrasonic irradiation were obviously lower than by ultrasonic irradiation and Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ films in the same conditions. The sonocatalytic degradation reactions of C.I. 50040, C.I. Reactive Red 1, and C.I. Acid Orange 7 by ultrasonic irradiation and by ultrasonic irradiation cooperating with $Co/N/Er^{3+}$: Y₃Al₅O₁₂/TiO₂ films followed the first-order kinetics by differential method.

SAŽETAK

Sinteza, karakterizacija i sonokatalitička aktivnost filmova Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ za razgradnju organskih bojila

Lan Wang,* Junling Ren i Changsheng Hao

Proučavana je sonokatalitička razgradnja organskih bojila (C.I. 50040, C.I. Reactive Red 1, C.I. Acid Orange 7) kataliziranih filmovima Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂. Za pripravu filmova Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ korišten je sol-gel proces premazivanja. Fazni sastav, morfologija, prekursor na različitim temperaturama i svojstva emitiranja svjetlosti kalciniranog praška analizirani su rendgenskom difrakcijom (XRD), apsorpcijskim spektrom i emisijskim spektrom uzlazne pretvorbe. Rendgenska analiza praškastih uzoraka Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ obuhvatila je svjetlosni agens uzlazne pretvorbe. Analiza apsorpcijskog spektra amorfnog $Co/N/Er^{3+}$: Y₃Al₅O₁₂/TiO₂ pokazala je da je dopiranjem N maksimuma vibracije istezanja vode ili hidroksilne apsorpcije, Co2+ ion imao vrlo jaku apsorpciju pri valnoj duljini od 1.0 – 1.7 μm, a tranzicijska luminiscencija Er^{3+} iona bila je samo na apsorpcijskoj vrpci Co^{2+} iona. Emisijski spektar pokazao je da $Co/N/Er^{3+}$: $Y_3Al_5O_{12}/TiO_2$ može emitirati zeleno 500 – 560 nm, crveno 650 – 700 nm te maksimume od 525, 550 i 660 nm koji odgovaraju prijelazima ${}^2H_{11/2}$, ${}^4S_{3/2} \rightarrow {}^4l_{15/2}$ i ${}^{4}H_{9/2} \rightarrow {}^{4}I_{15/2}$ za Er^{3+} . Dopirani Co i N pojačali su luminiscenciju uzlazne pretvorbe i apsorpcijski učinak. Učinak sonokatalitičke razgradnje organskih bojila s filmovima Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ bio je bolji kad je ultrazvučni intenzitet bio jednak 15 W cm⁻². Razgradni omjeri vodenih otopina ovih triju vrsta organskih bojila ultrazvučnim ozračenjem bili su znatno niži od ultrazvučnog ozračenja zajedno s filmovima Co/N/Er³⁺ : Y₃Al₅O₁₂/TiO₂ pri istim uvjetima. Kinetika razgradnje organskih bojila ultrazvučnim ozračenjem i ultrazvučnim ozračenjem s filmovima $Co/N/Er^{3+}$: Y₃Al₅O₁₂/TiO₂ pratila je reakciju prvog reda.
